About object schemas

An object schema is a collection of object types that serve a specific purpose, as well as the attributes, objects, permissions, icons, references, statuses, and automation rules associated with these object types.

Here’s an object schema that holds information about an ITSM (IT Service Management) configuration. Each of the icons below reflects an object type, and each line shows a reference that connects object types.

You can create as many object schemas as you like, and every schema can have its own set of permissions, allowing you to hide or show different schemas for different users.
